Business Case: Stop Automated Nike Shopping Agents

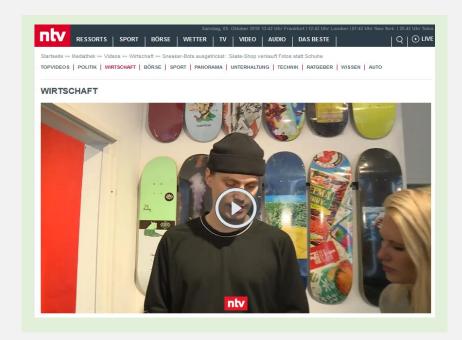

Business Case: Stop Automated Nike Shopping Agents

01 | Executive Summary

Limited sneakers can be resold profitably. Professional resellers use AI-based agents that can make automated purchases. Today, there are many AI-based agents and web-crawler that are able to detect and buy limited sneakers or other limited offers in web-shops, while normal customers often go away empty-handed. Furthermore, these kind of information systems produce a lot of web traffic (especially if they are very bad designed), and most shop-owners do not want them. A sneaker shop in Frankfurt has now outwitted the software. With a simple but ingenious idea.

02 | Solution

- Most simple AI agents use simple decision rules for decision-making.
- Hence, they lack of "true" intelligence and can be fooled easily by targeting on the decision-rules of such systems

03 References

Take-Aways

- AI-based agents can be used to automate human tasks (find cheap offers)
- However, they can not replace humans if it gets difficult

2.1 "Intelligent" Agents (Russel, Norvig)

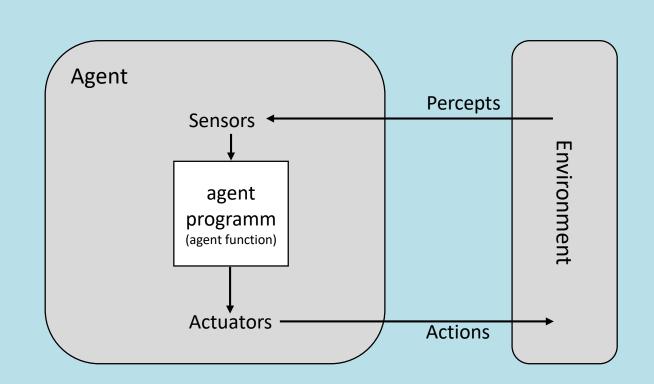

2.1 What Makes Agents Intelligent?

An agent is anything that can be viewed as perceiving its environment through sensors and acting upon that environment through actuators (Rusell & Norvig, 2016)

- An agent's behavior is described by the agent function that maps any given percept sequence to an action.
- We could imagine this as a table matching each possible percepts and actions (remember chinese room argument?)
- Internally, the agent function is implemented by an agent program

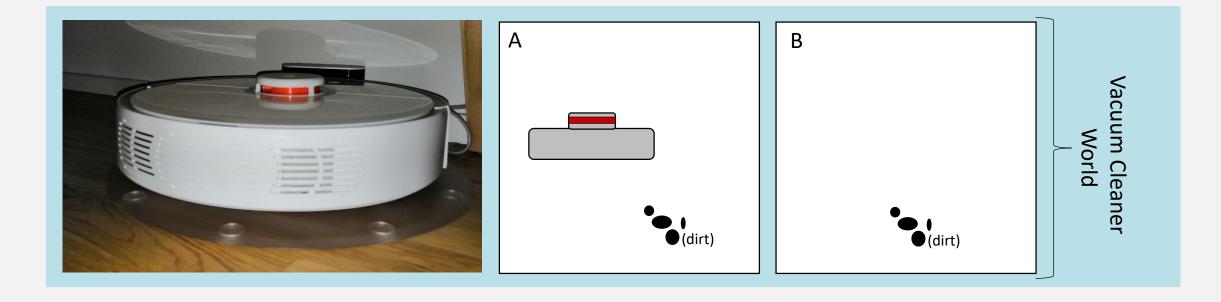

Adapted from Rusell, S., & Norvig, P. (2016) | Image source: 7 Pixabay (2019) / 7 CCO

How do you design an intelligent agent?

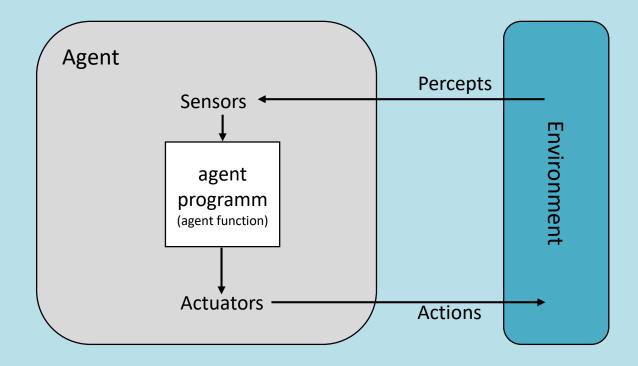

2.1 Example: Vacuum Cleaner World - Tabulation

- We use a very simple example: the vacuum-cleaner world with just two squares (A and B)
- The vacuum cleaner agent perceives which square it is and whether there is dirt or not
- It can move (left or right), suck up the dirt or do nothing.
- One simple function is: If the current square is dirty, then suck

2.1 Step 1 – Specifying the task environment

How does the task and the environment in which the task should be solved look like?

2.1 Specifying the task environment

Agent Type	Performance Measure	Environment	Actuators	Sensors
Taxi driver	Safe, fast, legal, comfortable trip, maximize profits	Roads, other traffic, pedestrians, customers	Steering, accelerator, brake, signal, horn, display	Cameras, sonar, speedometer, GPS, odometer, accelerometer, engine sensors, keyboard

- Norvig and Russel propose to characterize the task environment based on the four characteristics: Performance, Environment, Actuators and Sensors (PEAS)
- In designing an agent, the first step must always be to specify the task environment as fully as possible.

2.1 Further Properties of Task Environments

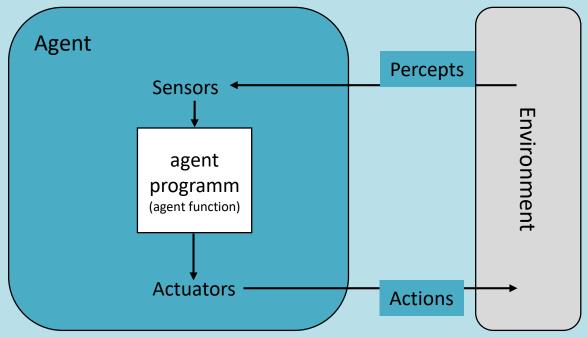

- Fully observable or partially observable
- Single agent or multiagent
- Deterministic or stochastic
- Episodic or sequential
- Static or dynamic
- Discrete or continuous
- Known or unknown

			5		01.11	- · ·
Task Environment	Observable	Agents	Deterministic	Episodic	Static	Discrete
Crossword puzzle	Fully	Single	Deterministic	Sequential	Static	Discrete
Chess with a clock	Fully	Multi	Deterministic	Seqential	Semi	Discrete
Poker	Partially	Multi	Stochastic	Sequential	Static	Discrete
Backgammon	Fully	Multi	Stochastic	Sequential	Static	Discrete
Taxi driving	Partially	Multi	Stochastic	Sequential	Dynamic	Continous
Medical diagnostics	Partially	Single	Stochastic	Sequential	Dynamic	Continous
Image Analysis	Fully	Single	Deterministic	Episodic	Semi	Continous
Part-Picking Robot	Partially	Single	Stochastic	Episodic	Dynamic	Continous
Refinery Controller	Partially	Single	Stochastic	Sequential	Dynamic	Continous
Interactive English Tutor	Partially	Multi	Stochastic	Sequential	Dynamic	Discrete

2.1 Step 2 – Specifying the agent

Agent = architecture + program

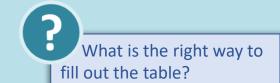

How should the agent act, what would be "intelligent behaviour"?

2.1 Example: Vacuum Cleaner World

Percept Sequence	Action
[A, Clean] [A, Dirty] [B, Clean] [B, Dirty] [A, Clean], [A, Clean] [A, Clean], [A, Dirty]	Right Suck Left Suck Right Suck
[A, Clean], [A, Clean], [A, Clean] [A, Clean], [A, Clean], [A, Dirty]	Right Suck

2.1 Good Behaviour: Conceptionalizing Rationality in Al

For a vacuum cleaner: What does it mean to do the right thing?

- What is rational at any given time depends on four things:
 - The performance measure that defines the criterion of success.
 - The agent's prior knowledge of the environment.
 - The actions that the agent can perform.
 - The agent's percept sequence to date

Rational Agent

For each possible percept sequence, a rational agent should select an action that is expected to maximize its performance measure, given the evidence provided by the percept sequence and whatever built-in knowledge the agent has (Rusell & Norvig, 2016, p.37)

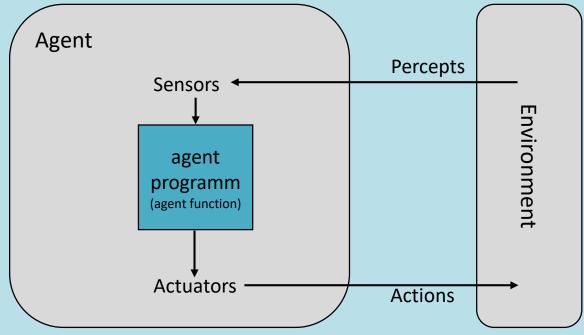

2.1 Omniscience, learning, and autonomy

- We need to be careful to distinguish between rationality and omniscience
- Rationality maximizes expected performance, while perfection maximizes actual performance
- Norvig & Russels' definition of rationality does not require omniscience, because the rational choice depends only on the percept sequence to date
- Their definition requires a rational agent not only to gather information but also to learn as much as possible from what it perceives.

2.1 Step 3 — Specifying the agents behaviour

Agent = architecture + program

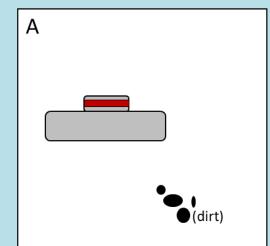

How can we implement the "intelligent" behaviour?

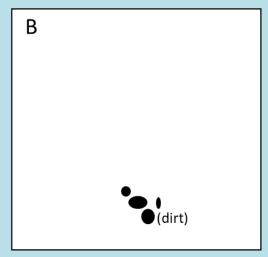

2.1 Structure of Agents (Architecture)

- The job of AI Specialists is to design an agent program that implements the agent function/the mapping from percepts to actions
- This program runs on some sort of computing device with physical sensors and actuators (architecture)
- Agent = architecture + program

2.1 Structure of Agents (Architecture)

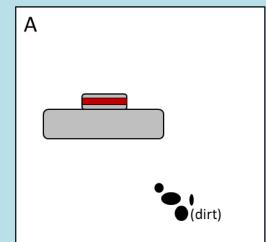

Algorithm: Reflex-Vacuum Agent

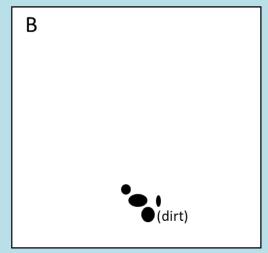

```
if status = dirty then
  return suck
end
```

else if location = A then
 return right
end

else if location = B then
 return left
end

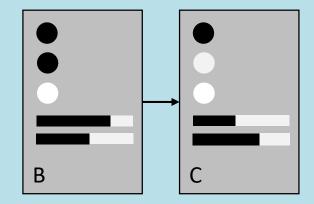

2.1 Components of Agents

Atomic representation

 a state (such as B or C) is a black box with no internal structure

Factored representation

 a state consists of a vector of attribute values; values can be Boolean, realvalued, or one of a fixed set of symbol

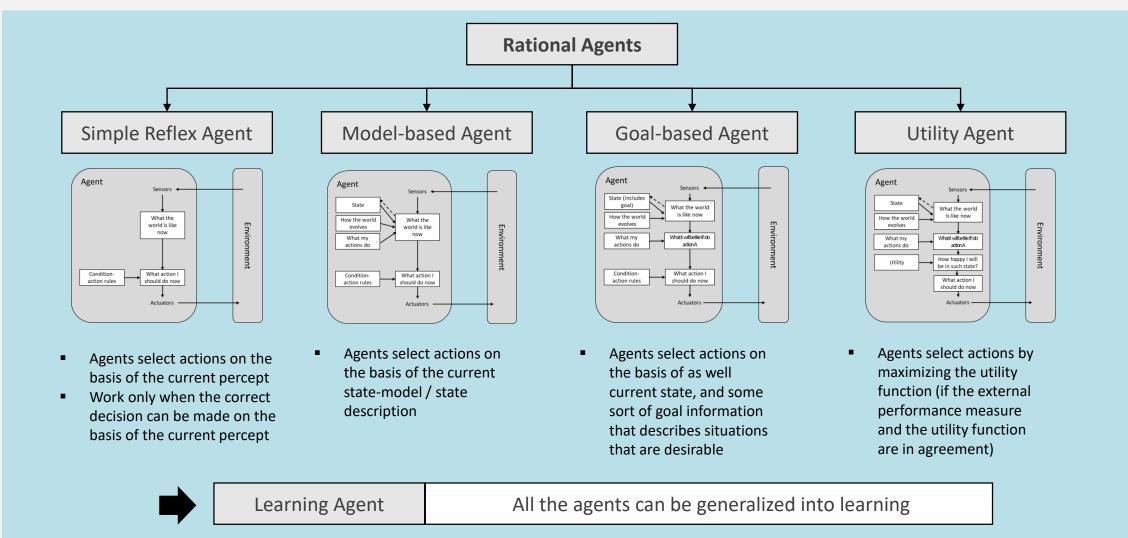

Structured representation

 a state includes objects, each of which may have attributes of its own as well as relationships to other objects.

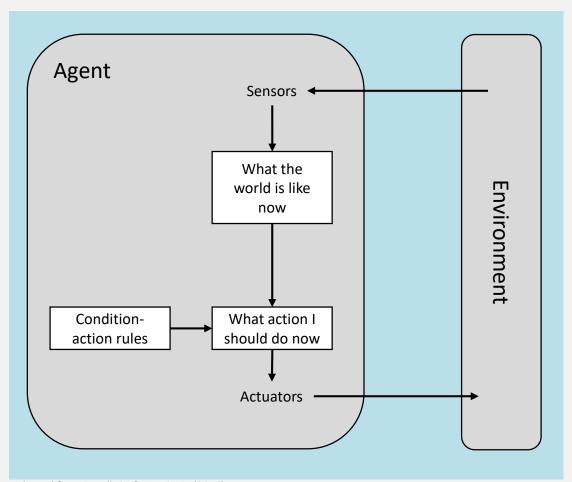

2.1 Subtypes of Agents (Russell & Norvig, 2016)

2.1 Simple Reflex Agent

▶ Select actions on the basis of the current percept, ignoring the rest of the percept history

Algorithm: Simple Reflex Agent

persistent: rules, a set of condition–action rules

 $state \leftarrow INTERPRET-INPUT(percept)$ $rule \leftarrow RULE-MATCH(state, rules)$ $action \leftarrow rule.ACTION$

2.1 Model-based Reflex Agent

► Keep track of the part of the world it can't see now

Algorithm: Model-based Reflex Agent

persistent:

state, the agent's current conception of the world state model, a description of how the next state depends on current state and action rules, a set of condition—action rules action, the most recent action, initially

 $state \leftarrow UPDATE-STATE(state, action, percept, model)$ $rule \leftarrow RULE-MATCH(state, rules)$ $action \leftarrow rule.ACTION$

2.1 Goal-based Agents

▶ Besides state description the agent uses goal information in its decision process

Algorithm: Goal-based Agent

persistent:

state, the agent's current conception of the world state model, a description of how the next state depends on current state and action

rules, a set of condition—action rules action, the most recent action, initially goal, desired result of the agents behaviour

state ← UPDATE-STATE(state, action, percept, model, goal)

 $rule \leftarrow RULE\text{-}MATCH(state, rules)$ $action \leftarrow rule\text{.}ACTION$

2.1 Utility-based Agent

► Utility function to describe desired behavior

Algorithm: Goal-based Agent

Utility function, performance measure

persistent:

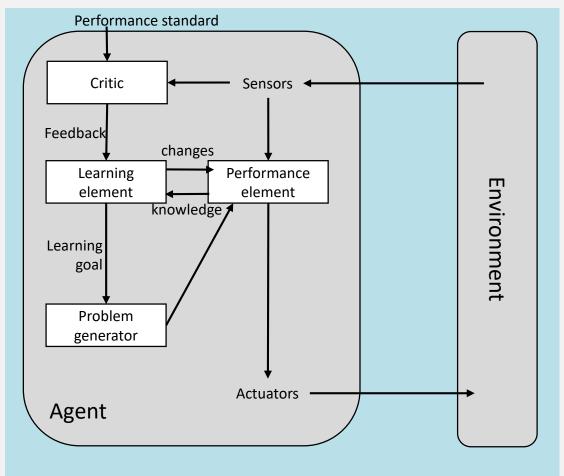

state, the agent's current conception of the world state model, a description of how the next state depends on current state and action rules, a set of condition—action rules action, the most recent action, initially

 $state \leftarrow UPDATE\text{-}STATE(state, action, percept, model, utility function)}$ $rule \leftarrow RULE\text{-}MATCH(state, rules)$ $action \leftarrow rule\text{-}ACTION$

2.1 Conclusion: The Learning Agent

► Agent improves its performance by learning optimal outputs

- A learning agent can be divided into four conceptual components: Learning element, performance element, critic, and problem generator
- The design of the learning element depends very much on the design of the performance element.
- The critic tells the learning element how well the agent is doing with respect to a fixed performance standard

2.1 Classroom task

Your turn!

Task

Please explain

- What is the difference between an agents program and function?
- Is a hand-held calculator an agent that chooses the action of displaying "3" when given the percept sequence "1 + 2 ="?

- **▶** Duration:
 - 120 min
- ► Relevant for Exam:
 - 2.1 2.3

2.2 Why we need Goals: Example Roadtrip Planning

- Example: USNationalpark roadtripwith your new Porsche
- Next step: How to formulate AI Problems and solve them

Adapted from Rusell, S., & Norvig, P. (2016) | Image source: ↗ Pixabay (2019) / ↗ CCO

2.2 Why we need Goals: Example Roadtrip Planning

Our problem can be defined formally by different aspects like:

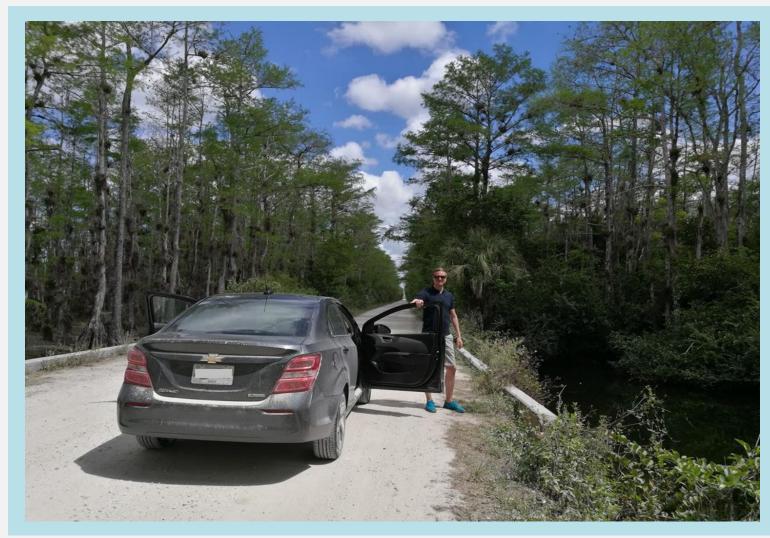

- Initial state or start
- Driving costs
- Visit Top 5 parks
- Music playlist
- Possible driving routes, allowed streets
- What each action does
- List with all parks to check if we got them all

→ Simplify Goal: Be in Shenandoah

2.2 Well-defined Problems and Solutions

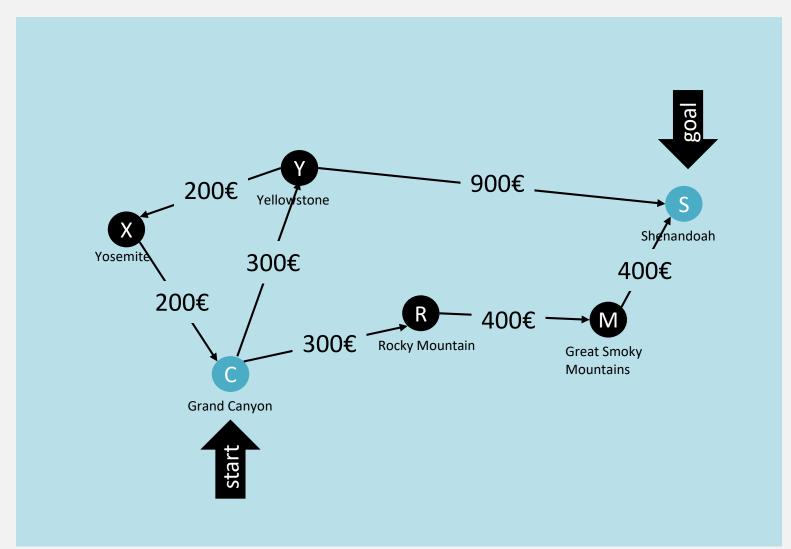

Let us now try to model our problem in a way an computer can solve it:

- In a first step, we want to build an agent that finds the optimal route from start to end (routefinding problem)
- Our second step is to have an agent that finds the optimal route for all Top 5 mainland US parks (touring-problem)

Adapted from Rusell, S., & Norvig, P. (2016) | Image source: ↗ Pixabay (2019) / ↗ CCO

2.2 Model the Roadtrip as an AI problem

Goal: Be in Shenandoah

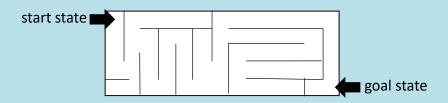

Other aspects:

- Initial state or start: Grand Canyon
- Consider Driving costs
- Visit Top 5 parks

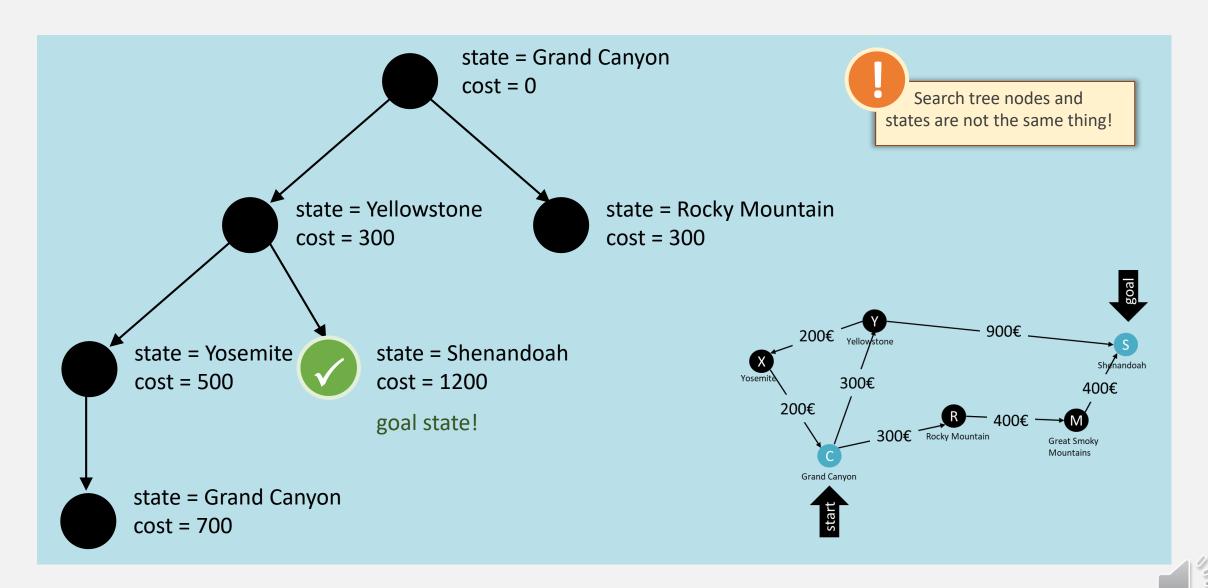

2.2 Possible Solution: Model Roadtrip-Problem as Search

- Model problems as search problems
- Our agent has not to execute all actions in real life while searching for solution
- We want to find a sequence of actions that will lead us to a desired state
 - We want to minimize number of actions
 - We want to minimize total cost of actions (more general speaking)

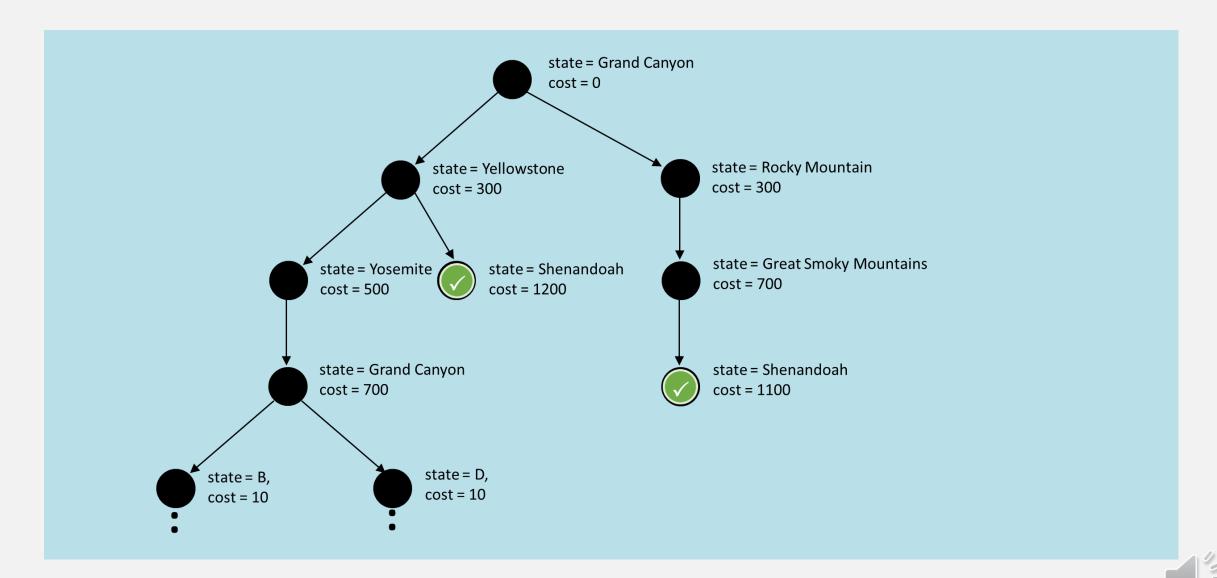

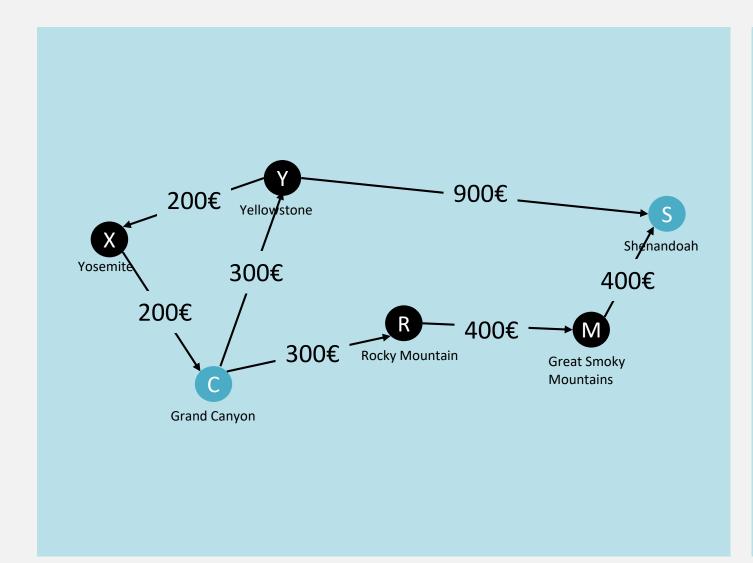

2.2 Model Problem as a Search-tree ▶ Step 1

2.2 Model Problem as a Search-tree ▶ Step 2

2.2 From Rout-Finding to Touring-Problems: Visit TOP 5 National parks

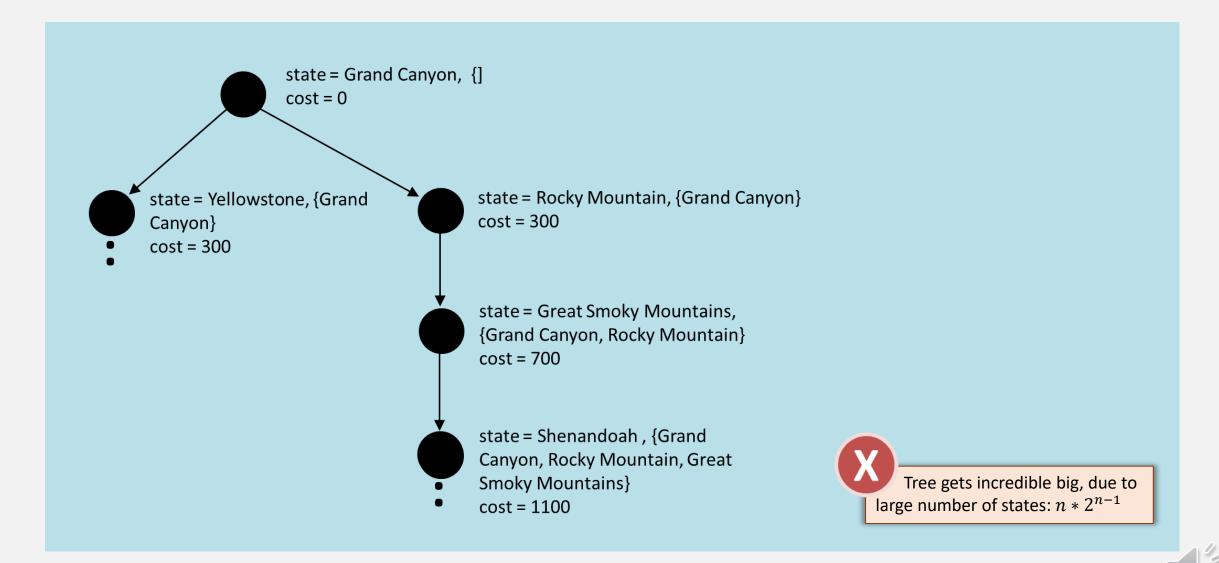

Goal: Visit all vertices on the graph

- As with before, the actions correspond to trips between adjacent parks.
- The state space is quite different: Each state must include not just the current location but also the set of cities the agent has visited.
- Problem: large number of states

2.2 Full search tree

2.2 Formulating Problems

- In the preceding section we proposed a simple formulation of the problem of planning an US roadtrip
- This formulation seems reasonable, but it is still an abstract mathematical simplification of a much more complex problem
- Many considerations are left out of our state descriptions because they are irrelevant to the problem of finding a route.
- The process of removing detail from a representation is called abstraction.
- Toy vs. real-world problem

2.2 Summary Key Concepts in Search

Set of **states** that we can be in

- Including an initial state
- and goal states (equivalently, a goal test)

For every state, a set of actions that we can take

- Each action results in a new state
- Typically defined by successor function

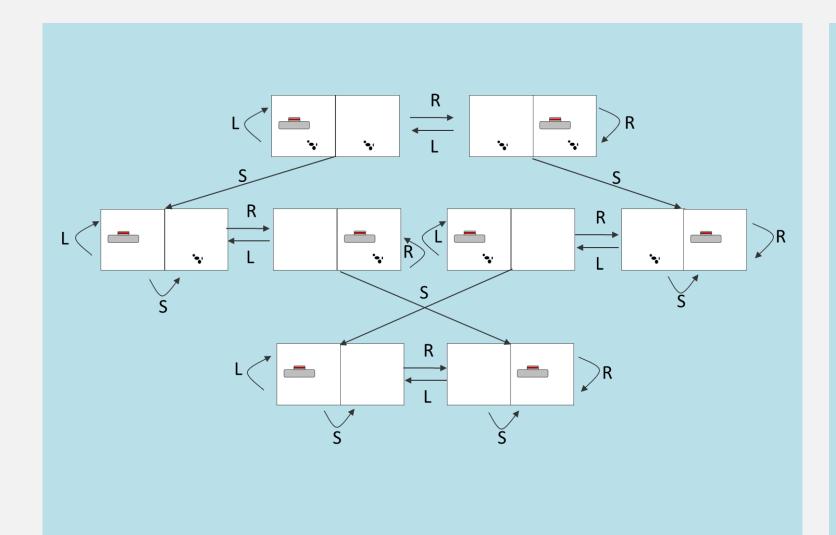

Transition model: Given a state, produces all states that can be reached from it

Cost function that determines the cost of each action (or path = sequence of actions)

Solution: path from initial state to a goal state (optimal solution: solution with minimal cost)

2.2 Example: Vacuum-Cleaner

- States: The state is determined by both the agent location and the dirt locations.
- Initial state: Any state can be designated as the initial state.
- **Actions**: *Left, Right,* and *Suck*.
- Transition model: The actions have their expected effects, except that moving Left in the leftmost square, moving Right in the rightmost square, and Sucking in a clean square have no effect.
- Goal test: This checks whether all the squares are clean.
- Path cost: Each step costs 1, so the path cost is the number of steps in the path.

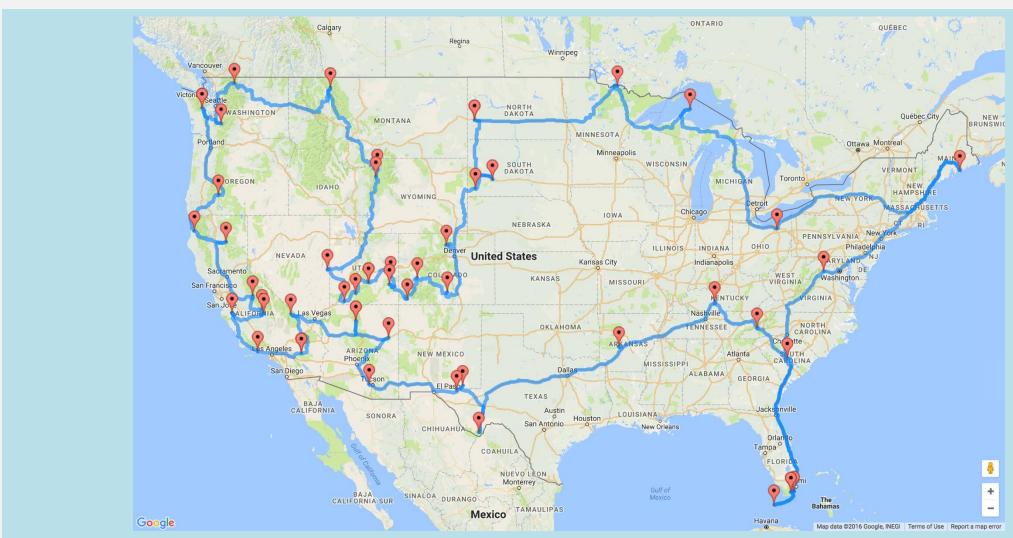

2.2 Other Popular Real-world Problems

- We tried to find
 - the optimal route from start to end (route-finding problem)
 - An optimal route for to visit all TOP 5 US parks (touring-problem)

The traveling salesperson problem (TSP) is a touring problem in which each city must be visited exactly once. The aim is to find the shortest tour.

2.2 Traveling Salesperson Problem of all 47 Mainland US Nationalparks

Credits for this route and Image source: 7 Dr. Randal Olson (2019)

2.2 Other Popular Real-world Problems

The traveling salesperson problem (TSP) is a touring problem in which each city must be visited exactly once. The aim is to find the shortest tour.

 A VLSI layout problem requires positioning millions of components and connections on a chip to minimize area, minimize circuit delays, minimize stray capacitances, and maximize manufacturing yield

■ **Protein design**: in which the goal is to find a sequence of amino acids that will fold into a three-dimensional protein with the right properties to cure some disease.

2.2 Generic Search Algorithm

- Recap: We will consider the problem of designing goal-based agents in observable, deterministic, discrete, known environments
- Key question in search: Which of the generated nodes do we expand next?

Algorithm: Tree Search

initialize the frontier using the initial state of problem

loop do

if the frontier is empty **then return** failure choose a leaf node and remove it from the frontier

if the node contains a goal state **then return** the corresponding solution

expand the chosen node, adding the resulting nodes to the frontier

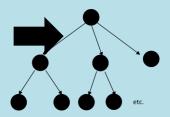

2.2 Overview: Fundamental Search Algorithms

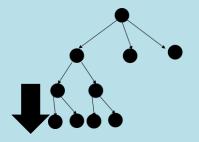

Uninformed Search

Strategies have no additional information about states beyond that provided in the problem definition

Breadth-first (BFS) Depth-first search (DFS)

Root node is expanded first, then all the successors of the root node are expanded next, then their successors, and so on.

 Always expands the deepest node in the current frontier of the search tree.

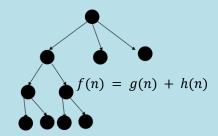

Informed Search

Uses problem-specific knowledge beyond the definition of the problem itself—can find solutions more efficiently than can an uninformed strategy.

 Expand the node that is closest to the goal, on the grounds that this is likely to lead to a solution quickly.

 Cluster observations into (distinct/different) groups

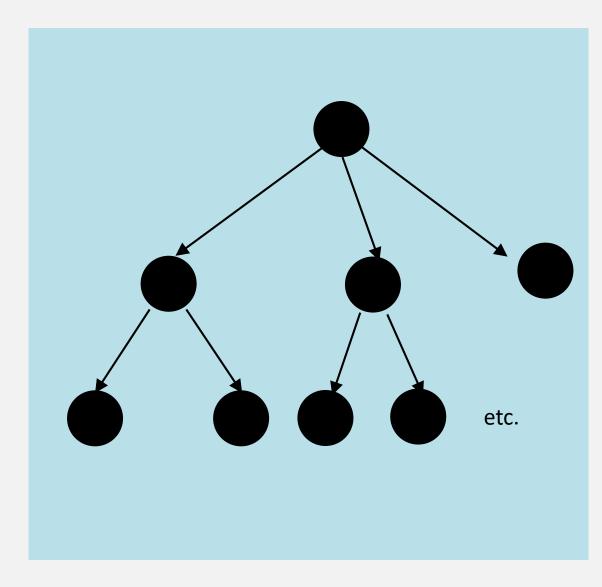

2.2 Uninformed Search

- Given a state, we only know whether it is a goal state or not
- Cannot say one non-goal state looks better than another non-goal state
- Can only traverse state space blindly in hope of somehow hitting a goal state at some point
 - Also called blind search
 - Blind does **not** imply unsystematic!

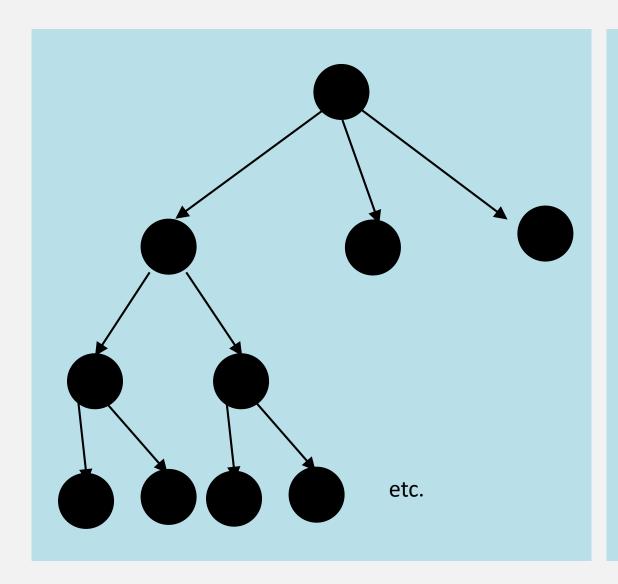

2.2 Breadth-first search

- Nodes are expanded in the same order in which they are generated
- Fringe can be maintained as a First-In-First-Out (FIFO) queue
- BFS is complete: if a solution exists, one will be found
- BFS finds a shallowest solution
- Not necessarily an optimal solution
- If every node has b successors (the branching factor), first solution is at depth d, then fringe size will be at least bd at some point
- This much space (and time) required !!!

2.2 Depth-first search

- Always expand node at the deepest level of the tree, e.g. one of the most recently generated nodes
- When hit a dead-end, backtrack to last choice
- Fringe can be maintained as a Last-In-First-Out (LIFO) queue (aka. a stack)

2.2 Let's start thinking about cost

■ Path costs: a function that assigns a cost to path, typically by summing the costs of the individual operators in the path. We want to minimize the cost.

 Search costs: The computational time and space (memory) required to find the solution

 There is a trade-off between path costs and search cost, in real-world-problems we can not build full search trees, we have to find best solution in the time available

2.2 Bidirectional search

• Even better: search from both the start and the goal, in parallel!

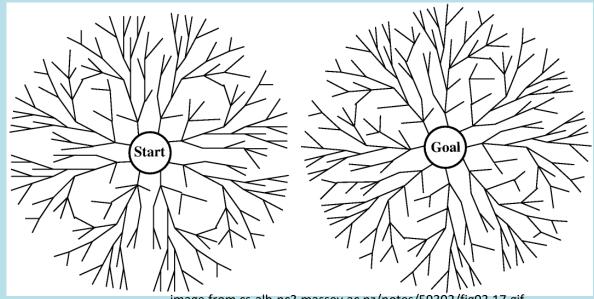

image from cs-alb-pc3.massey.ac.nz/notes/59302/fig03.17.gif

If the shallowest solution has depth d and branching factor is b on both sides, requires only O(bd/2) nodes to be explored!

2.2 Informed search

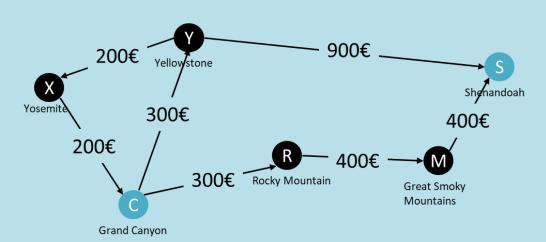

So far, have assumed that no non-goal state looks better than another

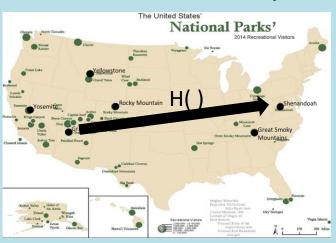

- Use knowledge to build search trees:
 - Even without knowing the road structure, some locations seem closer to the goal than others
 - Some states of a problem seem closer to the goal than others
- Makes sense to expand closer-seeming nodes first

2.2 Idea: Use an Criterion to identify which node to expand first

- Heuristic function h(n) gives an estimate of the distance from n to the goal (with h(n)=0 for goal nodes)
- E.g. straight-line distance for traveling problem (less costs for fuel etc.)

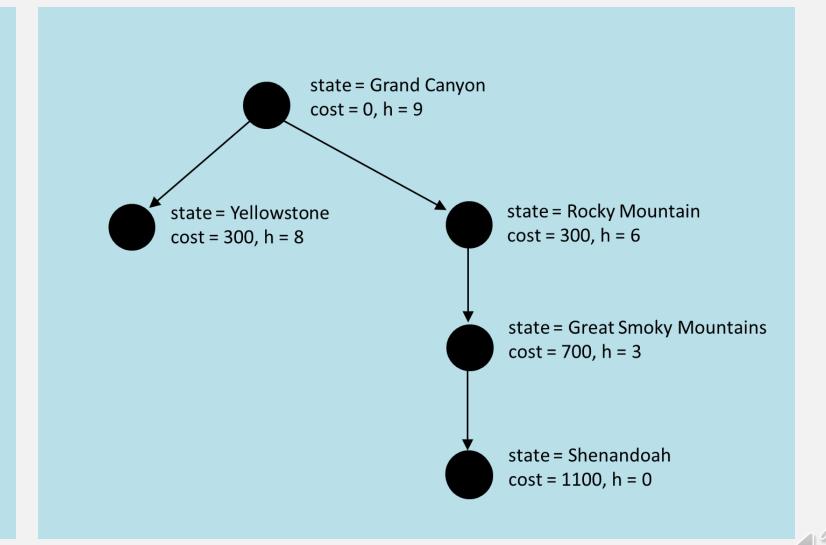

- We assume: h(C) = 9, h(Y) = 8, h(X) = 9, h(R) = 6, h(M) = 3, h(S) = 0
- Can use heuristic to decide which nodes to expand first

2.2 Greedy best-first search

 Greedy best-first search: expand nodes with lowest h values first

Can find fast an optimal soultion

2.2 A* search: Minimizing the total estimated solution cost

Evaluate nodes by combining g(n), the cost to reach the node, and h(n), the cost to get from the node to the goal:

$$f(n) = g(n) + h(n)$$

Since g(n) gives the path cost from the start node to node n, and h(n) is the estimated cost of the cheapest path from n to the goal, we have:

f(n) = estimated cost of the cheapest solution through n

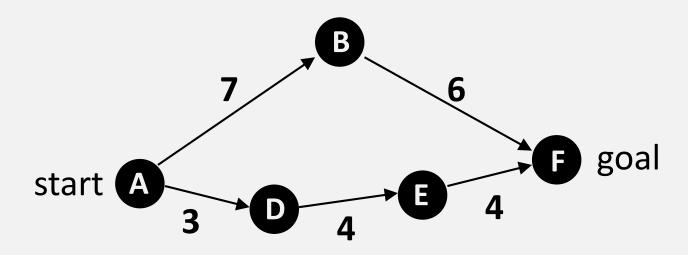

2.2 Classroom task

Your turn!

Task

Given the following route map with the following distance heuristics h(A) = 9, h(B) = 5, h(D) = 6, h(E) = 3, h(F) = 0. Try to solve this map with the greedy algorithm and discuss the results with your neighbors!

Outline

- 2 Problem-Solving Agents
- 2.1 Intelligent Agents
- 2.2 Solving Problems by Searching
- 2.3 Beyond Classical Search
- 2.4 Adversarial Search and Game Theory (forthcoming)
- 2.5 Constraint Satisfaction Problems (forthcoming)

► What we will learn:

- We define the concept of rational agents (≈ intelligent agents)
- Characteristics of artificial agents (perfect or otherwise), the diversity of environments, and the resulting menagerie of agent types
- We discuss how AI problems can be modelled as search-problems, and how they can be solved by searching

Image source:

☐ Pixabay (2019) / ☐ CCO

- **▶** Duration:
 - 120 min
- ► Relevant for Exam:
 - 2.1 2.3

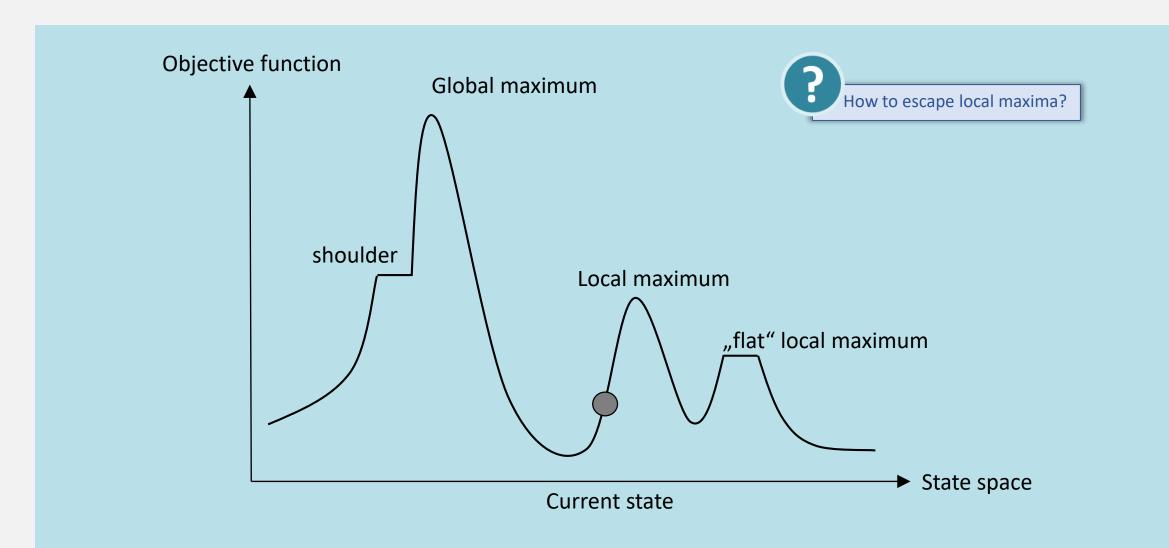

2.3 Beyond Classical Search

- Previous chapter: Path to goal is solution to problem
- But sometimes...
 - The start state may not be specified
 - The path to the goal doesn't matter
- In such cases, we can use local search algorithms that keep a single "current" state and gradually try to improve it

2.3 The state space "landscape"

2.3 How to Escape Local Maxima: Trivial Algorithms

- Random Sampling
 - Generate a state randomly

- Random Walk
 - Randomly pick a neighbor of the current state
- Both algorithms asymptotically complete

2.3 Local Search Algorithms

- If the path to the goal does not matter → simplify algorithms and ignore paths
- Local search algorithms are such algorithms, they use a single current node (rather than multiple paths) and generally move only to neighbors of that node
- Typically, the paths followed by the search are not retained. Although local search algorithms are not systematic, they have two key advantages:
 - they use very little memory usually a constant amount
 - they can often find reasonable solutions in large or infinite (continuous) state spaces for which systematic algorithms are unsuitable

2.3 Hill-climbing Search

Algorithm: Hill Climbing

 $current \leftarrow neighbor$

 $current \leftarrow MAKE-NODE(problem.INITIAL-STATE)$

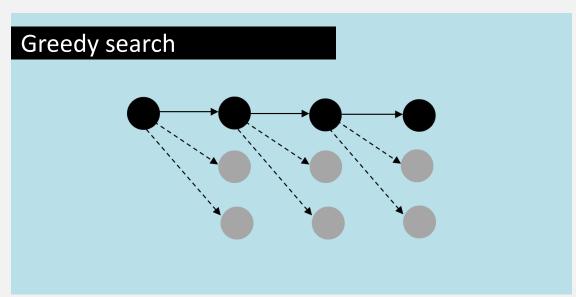

While STOP != TRUE
 neighbor ← a highest-valued succesor of cu
 rrent
 If neighbor.value ≤ current.VALUE
 Then return current. STATE

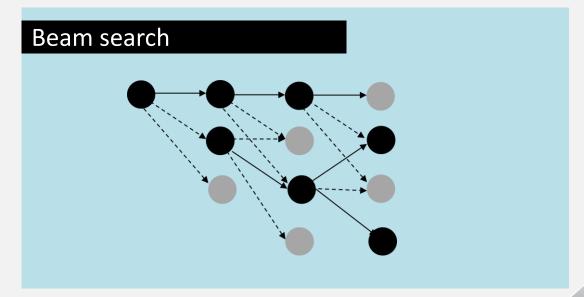

- Idea: simply a loop that continually moves in the direction of increasing value—that is, uphill
- The algorithm does not maintain a search tree, so the data structure for the current node need only record the state and the value of the objective function.
- Hill climbing does not look ahead beyond the immediate neighbors of the current state

2.3 Local Beam Search

- Start with k randomly generated states
- At each iteration, all the successors of all k states are generated
- If any one is a goal state, stop; else select the *k* best successors from the complete list and repeat

Adapted from Rusell, S., & Norvig, P. (2016);

2.3 Simulated Annealing Search

Algorithm: Simulated Annealing

Initialize current to starting state

For i = 1 to ∞ If T(i) = 0 return current

Let next = random successor of currentLet $\Delta = value(next) - value(current)$ If $\Delta > 0$ then let current = nextElse let current = next with $probability exp(\Delta/T(i))$

- Idea: Escape local maxima by allowing some "bad" moves but gradually decrease their frequency
- Probability of taking downhill move decreases with number of iterations, steepness of downhill move
- Controlled by annealing schedule
- Inspired by tempering of glass, metal

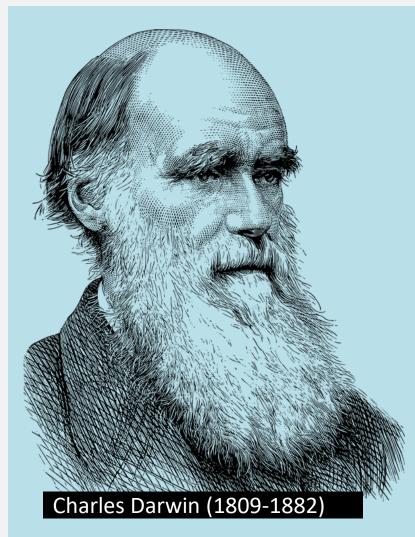

2.3 Conclusion: Simulated Annealing Search

- We can mathematically prove that a slow temperature decrease will find a global optimum with probability approaching one
- However:
 - This usually takes impractically long
 - The more downhill steps you need to escape a local optimum, the less likely you are to make all of them in a row
- State-of-the-Art: General family of Markov Chain Monte Carlo (MCMC) algorithms for exploring complicated state spaces

2.3 Genetic/Evolutionary Algorithms

Biological evolutionary model according to Darwin:

Selection = driving force of evolution

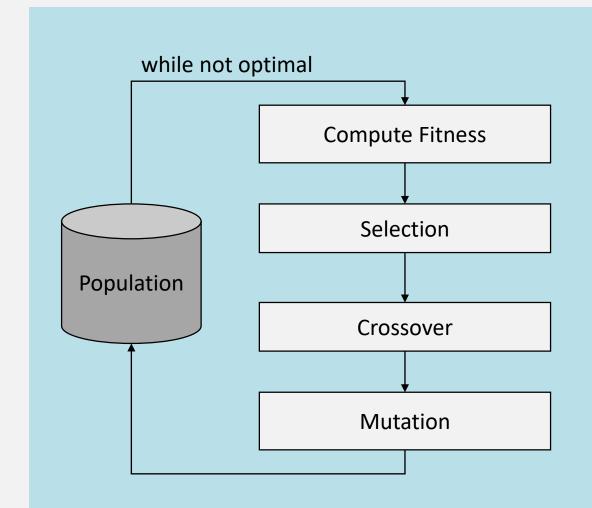

- Transfer to Computer Science: Evolution as optimization of complex, artificial systems
- Build machines that adapt to an defined working environment

2.3 Wording in Evolutionary Algorithms

Individual	Possible	e solution, hypothesis, or configuration
Population and ger	neration Set of s	olutions or hypothesis
Generation of desc		tion of new hypotheses. Methods: ination (Cross-over) and mutation
Changed successor offspring	c, child New hy	pothesis or configuration
Fitness function	Hypoth	esis quality, criterion to be optimized
Selection of the be		on of the hypotheses that the create the oblem solution

2.3 Basic Algorithm

Algorithm: Genetic Algorithm

Inputs: population, fitness_func

new_population <- empty set</pre>

Repeat

For i = 1 to SIZE(population) **do**

 $X \leftarrow RANDOM\text{-}SELECTION(population, fitness_func)$

 $Y \leftarrow RANDOM\text{-}SELECTION(population, fitness_func)$

 $Child \leftarrow REPRODUCE(x,y)$

If(random prob) then child \leftarrow MUTATE(child)

Add child to new_population

Population ← new_population

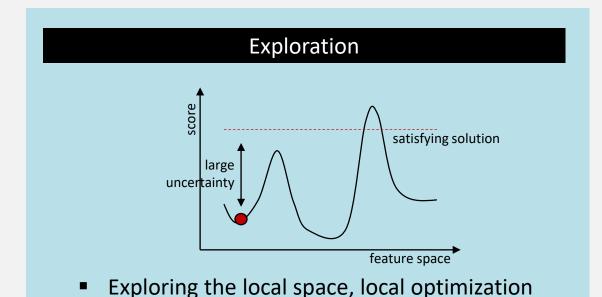

Until some individuals optimal or time elapse

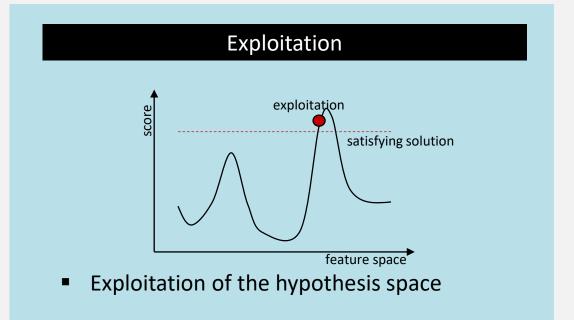

Return the best individuals in pop, according fitness_func

^{*}Reproduce returns an new individual

2.3 Generation of descendants

- The stronger and more random changes are, the lower the Probability to produce better offsprings
- With local improvement methods, the risk of local Minima given
- level of exploration must be in accordance with the current fitness of the generation can be selected (e.g.: initially high then falling)

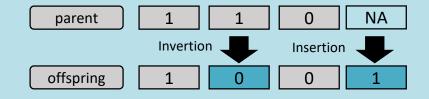

2.3 Mutation

Mutation

The offspring is descended from one parent, with mutation of single gene

Mutation:

- All bits of a sequence are independently inverted with a certain probability
- For a certain (or random) number of bits the indices are selected randomly
- Remove a partial sequence and insert it at another Place
- Inverted insertion of the partial sequence

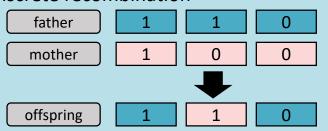

Crossover / Recombination

Mix properties of two or more parents

Crossover:

Discrete recombination

Intermediate recombination (continuous representation)

$$parent_1 := x \text{ and } parent_2 := y,$$

 $offspring_i := (x_i + y_i)/2$

2.3 Crossover/Recombination

Single-point Crossover

Two-point Crossover

Uniform Crossover

2.3 Selection

2 types of selection:

- of the parents for respective production of offspring (Mating)
- of the population in each iteration

Problems:

- Genetic drift: Individuals reproduce more than others by chance
- Crowding, outlier problem: "fit" individuals and similar offspring dominate the Population
- → Development of individuals is slowed down
- → Diversity of the population is restricted

Solution:

- Different population models and selection methods
- Optimize population size

2.3 Population models

- Island model (local)
 The evolution runs largely separately, only sometimes individuals exchanged
- Neighborhood model (near surroundings)
 Descendants may only be produced by individuals who are have the best fitness in their neighborhood
- A simple set (global)
 The best in the world are developing rapidly, others Lines of development are suppressed

2.3 Population members

Population size:

- Should it remain constant? (μ)
- How many newly produced offspring? (λ)
- How many parents should be used? (ρ)
- How are they determined?

Member selection:

stochastically selected \Rightarrow the best μ individuals

- $-(\mu, \lambda)$ Strategy: Selection refers only to the Offspring (better exploration)
- $(\mu + \lambda)$ Strategy:

Selection also involves parents (the Best are considered, search for Elites → Exploitation, cheap with good calculable fitness functions)

2.3 Classroom task

Your turn!

Task

Please explain

• What is the difference between the steps mutation and crossover in the context of genetic algorithms?

Exercises

Workbook Exercises

■ Please read the chapters 2-4 from Rusell, S., & Norvig, P. (2016). Work through the exercises of the related chapters. You can focus on the algorithms we discussed during lecture.

Coding Exercises

Coding exercises start after lecture 3

■ If you are also interested in visiting all US national parks, I can recommend to take a look at the blog article from *University* of Penn data scientist Dr. Randal Olson (http://www.randalolson.com). He created a roadtrip of the optimal way to visit all 47 U.S. National Parks in the mainland United States. Take a look at his Python Project (Github).

Glossary

Agent An agent is anything that can be viewed as perceiving its environment through sensors and acting

upon that environment through actuators (Rusell & Norvig, 2016)

Agent program Implements the agents function (Rusell & Norvig, 2016, p.59)

Performance measure Evaluates the behavior of the agent in an environment. A rational agent acts so as to maximize

the expected value of the performance measure, given the percept sequence it has seen so far

(Rusell & Norvig, 2016, p.59)

Rationality/Rational For each possible percept sequence, a rational agent should select an action that is expected to

Agent maximize its performance measure, given the evidence provided by the percept sequence and

whatever built-in knowledge the agent has (Rusell & Norvig, 2016, p.37)

Task environment External environment of an agent including the performance measure, the external environment,

the actuators, and the sensors (Rusell & Norvig, 2016, p.59)
